1 Preface

This is the protocol for the paper “Trends in incidence of young-onset diabetes by diabetes type: a multi-national population-based study” (cite). The methods used in this analyses are drawn heavily/almost entirely from Bendix Carstensen (see [1, 2]). To generate this document, the Stata package texdoc [3] was used, which is available from: <http://repec.sowi.unibe.ch/stata/texdoc/> (accessed 14 November 2022). The final Stata do file and this pdf are available at: <https://github.com/jimb0w/YO>. The ordinal colour schemes used are *inferno* and *viridis* from the *viridis* package [4].

2 Crude rates

We start by examining crude incidence rates for each country. We will generate a table showing the overall counts for each country, then plots of the crude incidence of each type of diabetes by sex and year. Also, because the diabetes type definitions require two years of non-insulin use to be effective, we will drop all data from 2021 or later.

3 Age and sex-specific rates

For the analyses, we are going to use Carstensen's Age-Period-Cohort model [2] to estimate the age and sex-specific incidence rates of type 2 diabetes for each country. For this, we take the incidence and person-years in 5-year age groups, and fit a Poisson model with spline effects of age, period (calendar time; measured from 2010 (i.e., 2010 is set to 0)), and cohort (calendar time minus age). This is done separately for each country and sex.

Knot number was determined iteratively and selected based on best fit (and knot placement is based on evenly spaced quantiles of the data as recommended by Harrell [5]). Best fit was determined based upon visual inspection of the relationship between modeled and crude rates, as well as inspection of the Pearson residuals by age, period, and cohort. Moreover, because of the different years covered by each dataset, the knot locations are different for each country .

Then, we use this model to predict the incidence rates of diabetes by age and calendar time. These results are presented in figures showing the incidence rates of type 2 diabetes for each country.

To make comparison between countries easier, we will plot all curves for age 25 on the same graph (and 20 and 30, to see if there is any difference depending on the age selected; figures 3.25 - 3.27).

For these plots, we no longer use an ordinal colour scheme. We're using rainbow.

4 Age-standardized rates

Additionally, we will age-standardise the incidence rates to the European population in 2010. This will be done using the same Age-Period-Cohort models described above. In this analysis, we will take the predicted rates from these models (in single years) and use these in direct standardisation. However, to do this, we first need to convert the European standard population (available only in 5-year age groups) to 1-year age groups (using linear regression).

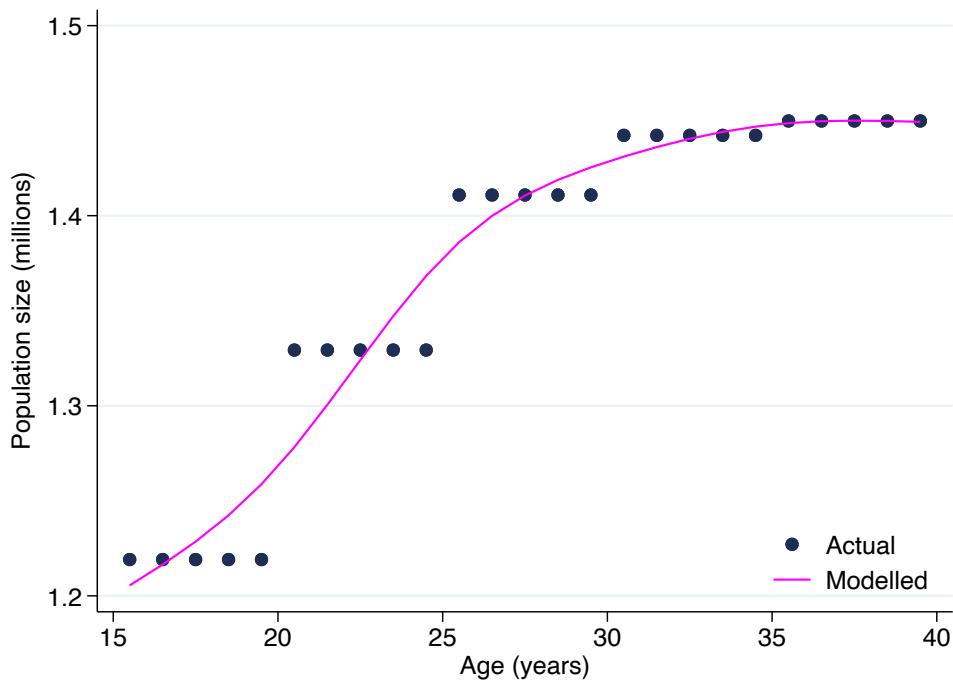

Figure 4.1: European standard population in 2010

```

use dbasev9, clear
drop if cal >= 2021
keep if _n<=5
keep age_gp esp2010
rename age_gp age
replace age = substr(age,1,2)
destring age, replace
expand 5
replace esp2010=esp2010/5
bysort age : replace age = age+.5
mkspline agesp = age, cubic knots(15(5)40)
reg esp2010 agesp*
predict A
preserve
replace esp2010 = esp2010/1000000
replace A = A/1000000
twoway ///
(scatter esp2010 age, col(dknavy)) ///
(line A age, col(magenta)) ///
, legend(symlinesize(0.13cm) position(4) ring(0) region(lcolor(white) color(none))) ///
order(1 "Actual" ///
2 "Modelled") ///

```

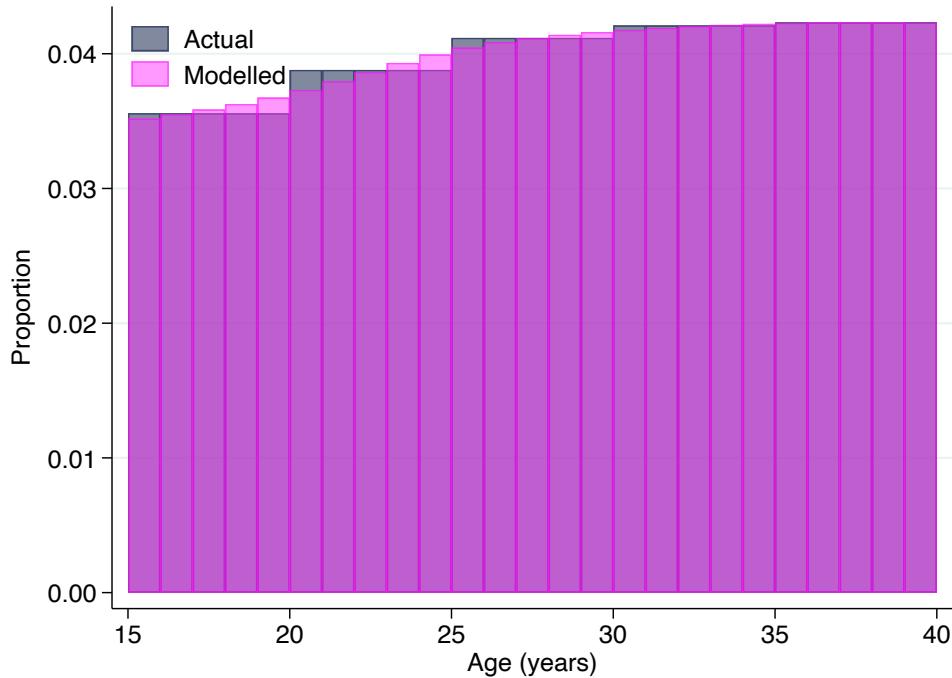

Figure 4.2: European standard population proportions in 2010

```

cols(1) ///
graphregion(color(white)) ///
ylabel(1.2(0.1)1.5, format(%9.1f) angle(0)) ///
ytitle("Population size (millions)" xtitle("Age (years)") )
restore
su(esp2010)
gen esp2010prop = esp2010/r(sum)
su(A)
gen B = A/r(sum)
twoway ///
(bar esp2010prop age, color(dknavy%70)) ///
(bar B age, color(magenta%50)) ///
, legend(symxsize(0.13cm) position(11) ring(0) region(lcolor(white) color(none))) ///
order(1 "Actual" ///
2 "Modelled") ///
cols(1) ///
ylabel(0(0.01)0.04, angle(0) format(%9.2f)) ///
graphregion(color(white)) ///
ytitle("Proportion" xtitle("Age (years)") )
keep age B
replace age = age-0.5
save refpop, replace
use dbasev9, clear
drop if cal >= 2021
keep if _n<=5
keep age_gp esp2010
rename age_gp age
replace age = substr(age,1,2)
destring age, replace
expand 5
replace esp2010=esp2010/5
bysort age : replace age = age+_n-0.5
mkspline agesp = age, cubic knots(15(5)40)

```

```
reg esp2010 agesp*
predict A
drop if age > 35
su(esp2010)
gen esp2010prop = esp2010/r(sum)
su(A)
gen B = A/r(sum)
keep age B
replace age = age-0.5
save refpop1, replace
```

With that, we can calculate and plot the age-standardized rates. Note: the method used to calculate the confidence intervals is the same as the Stata command dstdize, and it assumes that the person-years are the same for each single age within the 5-year age group (which, if the populations we sample from are anything like the European population, is a safe assumption (figure 4.2, and is unlikely to affect the calculated error even if included)).

5 Average Annual Percent Changes

As a summary metric, we will also estimate the average annual change in incidence - overall, and by sex. For this, we use a different model with a spline effect of age, but only a (log-)linear effect of calendar time. This means we are assuming the effect of time is constant throughout follow-up, which we already know is false for a few countries (e.g., Australia; figure 3.26).

```

It's also worth looking at variation in the incidence rates by age, as some of the figures in section 3 suggested a greater increase in type 2 diabetes at younger ages. For this, we will use two models: the first includes the interaction between a spline effect of age and a log-linear effect of calendar time (plotted in the left panels of the combined figures), whereas the second includes a spline effect of age and the product of log-linear effects of age and calendar time (plotted on the right in the figures).

6 Sensitivity analyses

6.1 Re-allocating uncertain diabetes type

In this sensitivity analysis, we will re-allocated people in the uncertain diabetes type category to either type 1 diabetes or type 2 diabetes, and assess the impact this has on age-adjusted trends and changes over time.
